

Edge AI for Remote Monitoring

A worked example deck, built by marp-deck from a vault note

June 2026

Why it matters

- Inference runs on site, so latency drops to the device round-trip
- Only results travel upstream, so bandwidth cost falls
- Raw data stays on the device, which improves privacy

Where it fits

- Remote monitoring of equipment, agriculture and infrastructure
- Sites far from reliable networks, where the cloud is not an option
- Limited on-device compute is the trade-off, which caps model size

What to watch

- Model drift is the main risk, so plan a retraining loop
- Power budget constrains solar or battery sites
- A diagram of the data path sits in the source note

References

The skill turns the note's wiki-links into a reference list:

- Bandwidth costs: the upstream data volume and its monthly cost
- Model drift: the slow loss of accuracy as field data shifts
